28.02.-05.03.2007

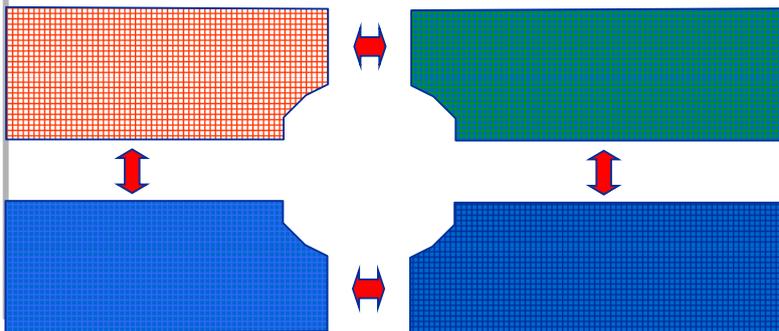

Programming Distributed-Memory Architectures *Schematic View*

- User explicitly distributes data
- User explicitly defines communication
- Compiler has to do no additional work

- Typically domain or work decomposition is used
- Typically communication across borders of domains is necessary

↑
User defined
communication

- The **same program** on each processor/machine (SPMD)
 - Restriction of the general MP model?
→ No, because processes can be distinguished by their **rank** (see later)
- The program is written in a sequential language (FORTRAN/C[++])

- All variables are local! → No concept of shared memory
- Data exchange between processes: **Send / Receive messages** via appropriate library
 - This is usually the most tedious but also the most flexible way of parallelization

- Widely accepted message passing standards:
 - **Message Passing Interface (MPI)**
 - **Parallel Virtual Machine** (actually MPMD) (waning importance..)

- **Messages: MP System moves data between processes**
- **MP System requires information about**
 - **Which processor is sending the message.**
 - **Where is the data on the sending processor.**
 - **What kind of data is being sent.**
 - **How much data is there.**
 - **Which processor(s) are receiving the message.**
 - **Where should the data be left on the receiving processor.**
 - **How much data is the receiving processor prepared to accept.**

- MPI library (MPI-1): 127 subroutine calls
 - For basic functionality: <10 needed!
- MPI Errors:
 - C MPI routines : Return an `int` — may be ignored
 - FORTRAN MPI routines : `ierror` argument — must not be omitted!
 - Return value `MPI_SUCCESS` indicates that all went ok
 - Default: Abort parallel computation in case of other return values
- Problem: Need include files/libraries at compile/link time!
 - Most implementations provide `mpif77`, `mpif90`, `mpicc` or `mpiCC` scripts for compile and link step
 - These facilities are not standardized, so variations are to be expected, e.g. with Intel-MPI (`mpiifort`, `mpiicc` etc.).

- Required header files:
 - C: `#include <mpi.h>`
 - FORTRAN: `include 'mpif.h'`
 - FORTRAN90: `USE MPI`
- Bindings:
 - C: `error = MPI_Xxxx(parameter,.....);`
 - FORTRAN: `call MPI_XXXX(parameter,...,ierror)`
 - MPI constants (global/common): Upper case in C
- Arrays:
 - C: indexed from 0 ↔ FORTRAN: indexed from 1
- Here: concentrate on FORTRAN interface!
- Most frequent source of errors in C: call by reference with return values!

- Each processor must start/terminate an MPI process
 - Usually handled automatically
 - More than one process per processor is often, but not always possible
- **First call in MPI program:** initialization of parallel machine!
`call MPI_INIT(ierror)`
- **Last call:** shut down parallel machine!
`call MPI_FINALIZE(ierror)`
(Only process with rank 0 (see later) is guaranteed to return)
- **ierror** = integer argument for error report
- Usually: stdout/stderr of each MPI process is redirected to console where program was started (but depending on implementation)

- Frequent source of errors: `MPI_Init()` in C
C binding:

```
int MPI_Init(int *argc, char ***argv);
```

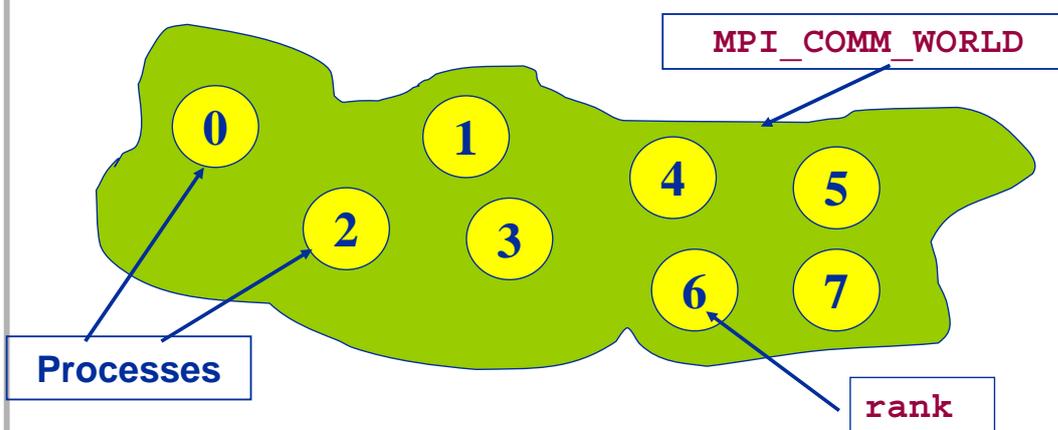

- If `MPI_Init()` is called in a function (bad idea anyway), this function must have pointers to the original data:

```
void init_all(int *argc, char***argv) {  
    MPI_Init(argc, argv);  
    ...  
}  
...  
init_mpi(&argc, &argv);
```

- Depending on implementation, mistakes at this point might even go unnoticed until code is ported

- `MPI_INIT` defines "communicator" `MPI_COMM_WORLD`:

- `MPI_COMM_WORLD` defines the processes that belong to the parallel machine
- `rank` labels processes inside the parallel machine

- The **rank** identifies each process within the communicator (e.g. **MPI_COMM_WORLD**):
 - Get rank with **MPI_COMM_RANK**:
`integer rank, ierror`
`call MPI_COMM_RANK(MPI_COMM_WORLD, rank, ierror)`
 - **rank** = 0,1,2,..., (number of processes – 1)

- Get number of processes within **MPI_COMM_WORLD** with:

```
integer size, ierror  
call MPI_COMM_SIZE(MPI_COMM_WORLD, size, ierror)
```

- **MPI_COMM_WORLD** is a global variable and required as argument for nearly all MPI calls
- **rank**
 - is target label for MPI messages
 - can define what each process should do:

```
call MPI_COMM_RANK(MPI_COMM_WORLD, rank, ierror)
```

```
...
```

```
if (rank.EQ.0)
```

```
    *** do work for rank 0 ***
```

```
else
```

```
    *** do work for other ranks ***
```

```
end if
```

```
program hello
implicit none
include 'mpif.h'

integer rank, size, ierror

call MPI_INIT(ierror)
call MPI_COMM_SIZE(MPI_COMM_WORLD, size, ierror)
call MPI_COMM_RANK(MPI_COMM_WORLD, rank, ierror)

write(*,*) 'Hello World! I am ',rank,' of ',size

call MPI_FINALIZE(ierror)
end
```

- Compile:

```
mpif90 -o hello hello.f90
```

- Run on 4 processors:

```
mpirun -np 4 ./hello
```

- Output:

```
Hello World! I am 3 of 4
Hello World! I am 1 of 4
Hello World! I am 0 of 4
Hello World! I am 2 of 4
```

Order undefined!

- Communication between two processes:
Sending / Receiving of MPI-Messages

- MPI-Message:
Array of elements of a particular MPI datatype

- MPI datatypes:
 - Basic datatypes
 - Derived datatypes

MPI datatype	FORTRAN datatype
MPI_CHARACTER	CHARACTER(1)
MPI_INTEGER	INTEGER
MPI_REAL	REAL
MPI_DOUBLE_PRECISION	DOUBLE PRECISION
MPI_COMPLEX	COMPLEX
MPI_LOGICAL	LOGICAL
MPI_BYTE	
MPI_PACKED	

MPI datatype	C datatype
MPI_CHAR / MPI_SHORT	signed char / short
MPI_INT / MPI_LONG	signed int / long
MPI_UNSIGNED_CHAR / ...	unsigned char / ...
MPI_FLOAT / MPI_DOUBLE	float / double
MPI_LONG_DOUBLE	long double
MPI_BYTE	
MPI_PACKED	

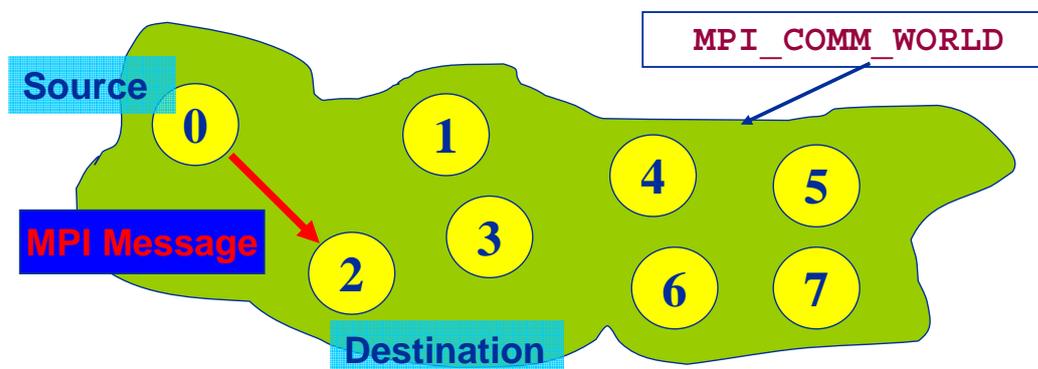

- **MPI_BYTE**: Eight binary digits: do not use
- **MPI_PACKED**: can implement new data types → however, derived data types are available to build new data type at run time from basic data types
- **Data-type matching**: Same MPI data type in SEND and RECEIVE call
 - Data types must match on both ends in order for the communication to take place
- Supports heterogeneous systems/clusters
 - Automatic data type conversion between heterogeneous environments

- Communication between **exactly** two processes within the communicator

- Identification of source and destination by the rank within the communicator!
- **Blocking**: MPI call returns if the message to be sent or received can be modified or used ...

- **Syntax (FORTRAN):**

```
MPI_SEND(buf, count, datatype, dest, tag, comm,  
ierror)
```

- **buf:** Address of data to be sent
 - **count:** Number of elements to be sent
 - **datatype:** MPI data type of elements to be sent
 - **dest:** Rank of destination process
 - **tag:** Message marker
 - **comm:** Communicator shared by source & destination
 - **ierror:** Error code
- **Completion of MPI_SEND: Status of *destination* is not defined: Message may or may not have been received after return!**
 - **Send buffer may be reused after MPI_SEND returns**

- **Example: first 10 integers of array *field* to process #5**

```
integer count, dest, tag, field(100)  
...  
count=10  
dest=5  
tag=0  
call MPI_SEND(field, count, MPI_INTEGER, dest, tag,  
& MPI_COMM_WORLD, ierror)
```

Source and destination may coincide, but: danger of deadlocks!

- **MPI_RECV:**
 - 1) Receive data
 - 2) Complete
- **Syntax (FORTRAN):**

```
MPI_RECV(buf, count, datatype, source, tag, comm,  
        status, ierror)  
  
integer status(MPI_STATUS_SIZE)
```

 - buf **Size of buffer must be \geq size of message !**
 - count **Maximum number of elements to receive**
 - source, tag **Wildcards may be used (MPI_ANY_SOURCE,**
 MPI_ANY_TAG)
 - status **Information from the message that was received**
 (size, source, tag) (Wildcards!)

- **Example: receive array of REALs from any source**

```
integer count, source, tag, status(MPI_STATUS_SIZE)  
real field(count)  
...  
call MPI_RECV(field, count, MPI_REAL,  
&          MPI_ANY_SOURCE, MPI_ANY_TAG,  
&          MPI_COMM_WORLD, status, ierror)  
write(*,*) 'Received from #', status(MPI_SOURCE),  
&          ' with tag ', status(MPI_TAG)
```

Get actual number of received items with MPI_GET_COUNT:

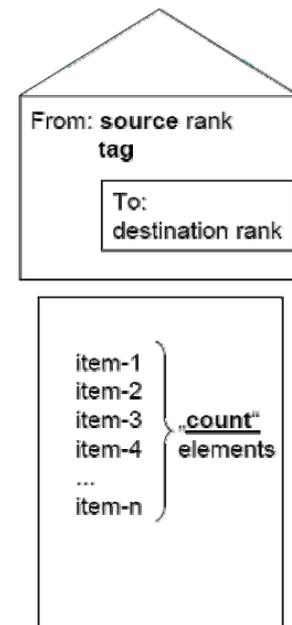

`MPI_GET_COUNT(status, datatype, count, ierror)`

For a communication to succeed:

- Sender must specify a valid destination.
- Receiver must specify a valid source rank (or `MPI_ANY_SOURCE`).
- Communicator must be the same (e.g. `MPI_COMM_WORLD`).
- Tags must match.
- Message data types must match.
- Receiver's buffer must be large enough.

- **Beginner's MPI procedure toolbox:**
 - `MPI_INIT` **let's get going**
 - `MPI_COMM_SIZE` **how many are we?**
 - `MPI_COMM_RANK` **who am I?**
 - `MPI_SEND` **send data to someone else**
 - `MPI_RECV` **receive data from some-/anyone**
 - `MPI_GET_COUNT` **how much have I received?**
 - `MPI_FINALIZE` **finish off**
- **Standard send/receive calls provide most simple way of point-to-point communication**
- **Send/receive buffer may safely be reused after the call has completed**
- **`MPI_SEND` has to have a specific target/tag, `MPI_RECV` does not**

- **Task: Write parallel program in which a master process („root“)
collects some data (e.g. numbers to sum up) from the others**

```
program collect
  implicit none
  include 'mpif.h'
  int i,size,rank,ierror,status(MPI_STATUS_SIZE)
  int number,sum

  call MPI_INIT(ierror)
  call MPI_COMM_RANK(MPI_COMM_WORLD,rank,ierror)

  if(rank.eq.0) then
    sum=0
    call MPI_COMM_SIZE(MPI_COMM_WORLD,size,ierror)
```

```
    do i=1,size-1
      call MPI_RECV(number,1,MPI_INTEGER, &
        MPI_ANY_SOURCE,MPI_ANY_TAG,MPI_COMM_WORLD, &
        status,ierror)
      sum=sum+number
    enddo
  write(*,*) 'The sum is ',sum
else
  call MPI_SEND(rank,1,MPI_INTEGER,0,0, &
    MPI_COMM_WORLD,ierror)
endif
call MPI_FINALIZE(ierror)
end
```

Blocking Point-to-Point Communication in MPI

Programming Distributed-Memory Architectures *Blocking Point-to-Point Communication*

- **“Point-to-Point communication”**
 - One process sends a message to another, i.e. communication between exactly two processes
 - Two types of point-to-point communication: Synchronous send vs. buffered = asynchronous send
- **“Blocking”**
 - Operations are local activities on the sending and receiving processes - may block one processes until partner process acts:
 - Synchronous send operation blocks until receive is posted
 - Asynchronous send blocks until message can be changed on sender process
 - Receive operation blocks until message is sent
 - After a blocking subroutine returns, you may change the buffer without changing the message to be sent

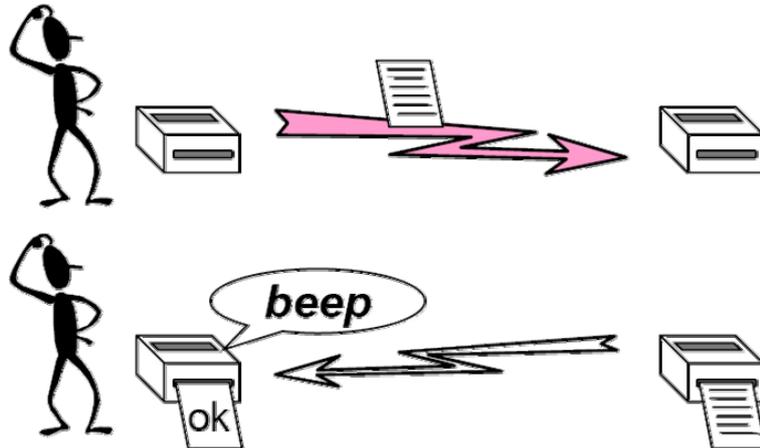

„Sending process“

- The sender gets an information that the message is received.

- Analogue to the beep or okay-sheet of a fax.

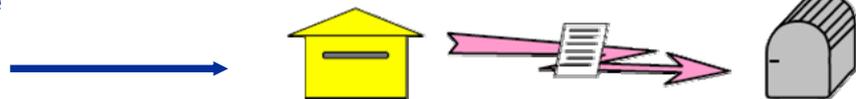

„Sending process“

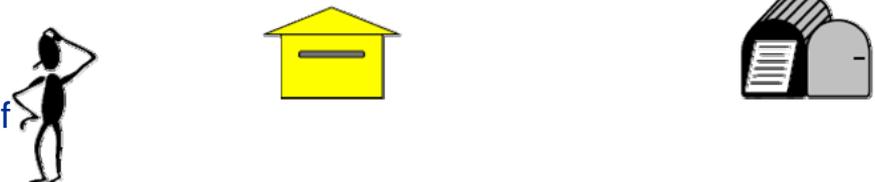

- One only knows when the message has left

- Message to be sent is put in a separate (system) buffer

- No need to care about the time of delivery.

- Completion of send/receive ↔ buffer can safely be reused!

Communication mode	Completion condition	MPI Routine (Blocking)
 Synchronous Send	Only completes when the receive has started.	MPI_SSEND
 Buffered Send	Always completes, irrespective of the receive process.	MPI_BSEND
 Standard Send	Either synchronous or buffered.	MPI_SEND
 Ready Send	Always completes, irrespective whether the receive has completed.	MPI_RSEND DONOT USE
Receive	Completes when a message has arrived.	MPI_RECV

- MPI_SSEND completes **after** message has been accepted by the destination (“handshaking”).
- Synchronization of source and destination!
- Predictable and safe behavior!
- MPI_SSEND should be used for debugging purposes!
- Problems:
 - Performance (high latency, risk of serialization – best bandwidth)
 - Deadlock situations (see later)
- Syntax (FORTRAN): same as MPI_SEND

```
MPI_SSEND( buf, count, datatype, dest, tag, comm,
           ierror)
```

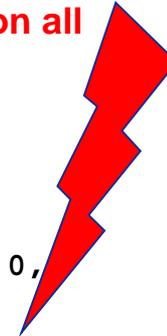

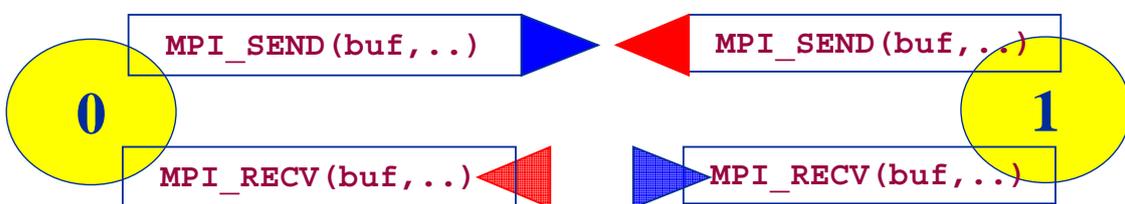

- Example with 2 processes, each sending a message to the other:

```
integer buf(200000)
if(rank.EQ.0) then
    dest=1
    source=1
else if(rank.EQ.1) then
    dest=0
    source=0
end if
MPI_SEND(buf, 200000, MPI_INTEGER, dest, 0,
& MPI_COMM_WORLD, ierror)
MPI_RECV(buf, 200000, MPI_INTEGER, source, 0,
& MPI_COMM_WORLD, status, ierror)
```

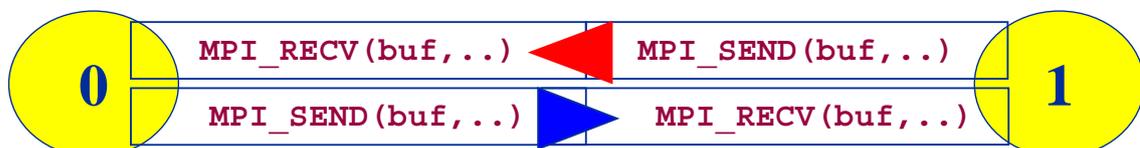

This program will not work correctly on all systems!

- Deadlock:** Some of the outstanding blocking communication cannot be completed (program stalls)
- Example:** `MPI_SEND` is implemented as **synchronous send** for large messages!

One remedy: reorder send/receive pair on one process (e.g. rank 0):

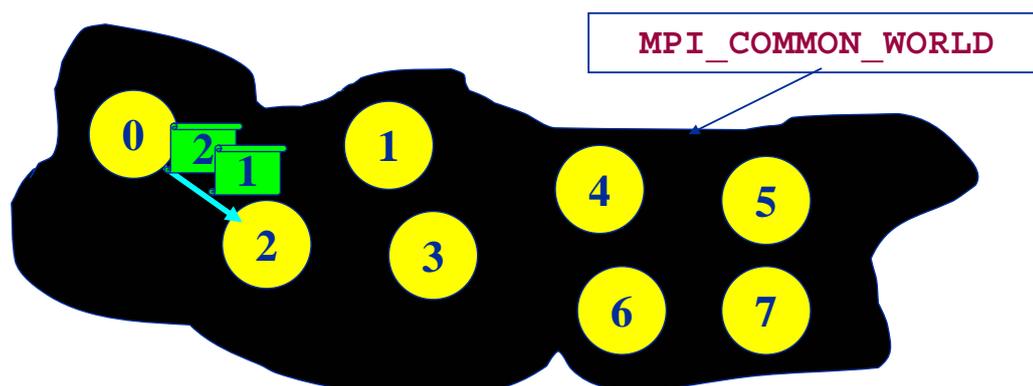

```
integer buf(200000), buf_tmp(200000)
if(rank.EQ.0) then
    dest=1
    source=1
    MPI_SEND(buf, 200000, MPI_INTEGER, dest, 0,
    & MPI_COMM_WORLD, ierror)
    MPI_RECV(buf, 200000, MPI_INTEGER, source, 0,
    & MPI_COMM_WORLD, status, ierror)
else if (rank.EQ.1) then
    dest=0
    source=0
    MPI_RECV(buf_tmp, 200000, MPI_INTEGER, source, 0,
    & MPI_COMM_WORLD, status, ierror)
    MPI_SEND(buf, 200000, MPI_INTEGER, dest, 0,
    & MPI_COMM_WORLD, ierror)
    buf=buf_tmp
end if
```

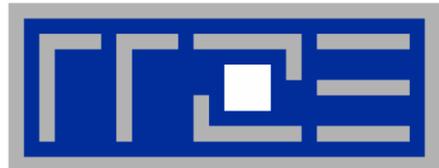

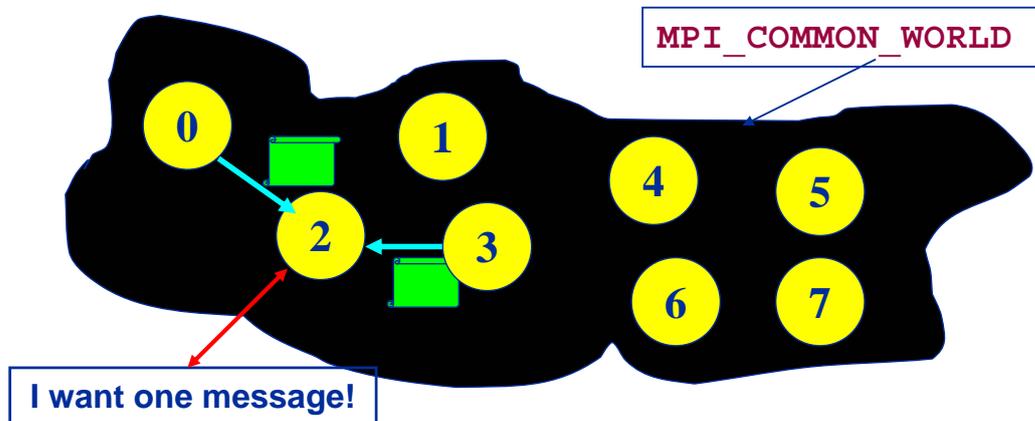

- Deadlocks are always introduced by the programmer!
- MPI semantics guarantees progress for standard compliant programs
- **Semantics:** Rules, guaranteed by MPI implementations
 - Message Order Preservation (within same communicator)

- **Progress:** It is not possible for a **matching** send and receive pair to remain permanently outstanding.
 - **Matching** means: data types, tags and receivers match

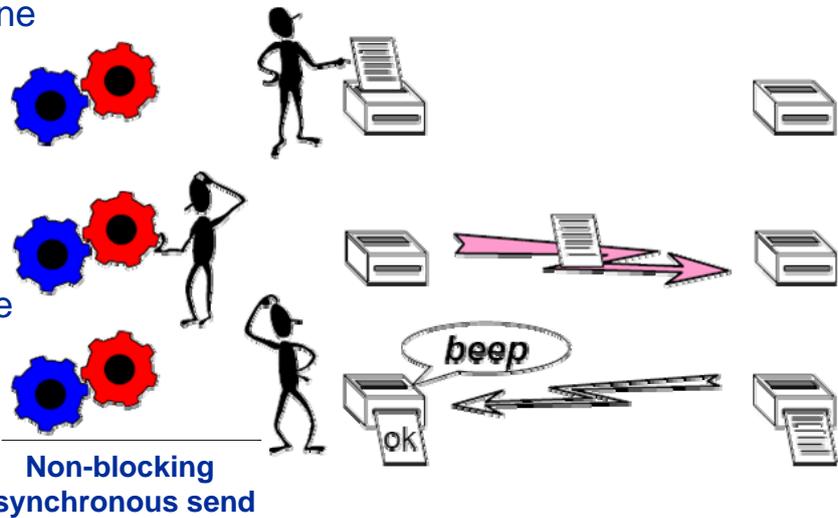

Non-Blocking Point-to-Point Communication in MPI

Idea of Non-Blocking Communication:
 Overlap communication & work and enhance flexibility

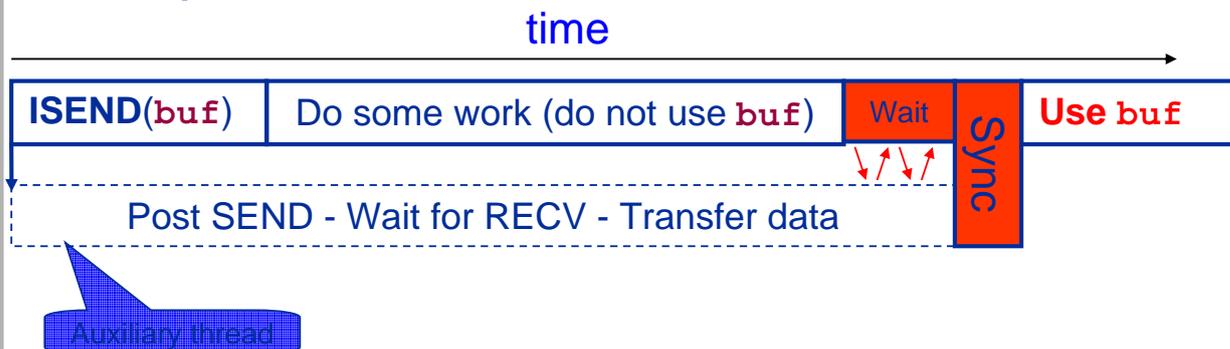

- After initiating the communication one can return to perform other work.

- At some later time one must **test** or **wait** for the completion of the non-blocking operation.

- Motivation:**
 - Avoid deadlocks
 - Avoid idle processors
 - Avoid useless synchronization
 - Overlap communication and useful work (hide the 'communication cost')
- Principle:**

- Detailed steps for non-blocking communication

- 1) Setup communication operation (MPI)
- 2) Build unique **request handle** (MPI)
- 3) Return **request handle** and control to user program (MPI)
- 4) User program continues while MPI system performs communication (asynchronously)
- 5) Status of communication can be probed by the **request handle**

All non-blocking operations must have matching wait (or test) operations as some system or application resources can be freed only when the non-blocking operation is completed.

- The return of non-blocking communication call **does not imply completion** of the communication
- Check for completion: Use **request handle** !
- **Do not reuse buffer** until completion of communication has been checked !
- Data transfer can be overlapped with user program execution (if supported by hardware)
- **Blocking send matches a non-blocking receive and vice-versa!**

- **Standard non-blocking send**
`MPI_ISEND(sendbuf, count, datatype, dest, tag, comm, request, ierror)`
request: integer argument as **request handle**
 - **Do not reuse** sendbuf **before** MPI_Isend has been completed!
- **Standard non-blocking receive**
`MPI_Irecv(recvbuf, count, datatype, source, tag, comm, request, ierror)`
 - **Do not reuse** recvbuf **before** MPI_Irecv has been completed!
 - **No status** array necessary – will be used in `MPI_WAIT/MPI_TEST`

- **Test one** communication for completion – basic calls:

```
MPI_WAIT( request, status, ierror);
```

```
MPI_TEST( request, flag, status, ierror);
```

Parameter:

- **request:** request handle
- **status:** status object (cf. `MPI_RECV`)
- **flag:** logical to test for success

- **Example: 2 processes, each sending a message to the other:**

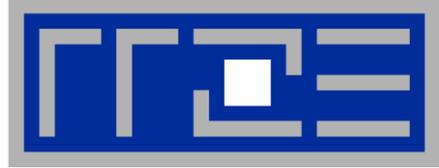

```
integer buf(200000), buf_tmp(200000)
if(rank.EQ.0) then
    dest=1
    source=1
else if(rank.EQ.1) then
    dest=0
    source=0
end if
MPI_ISEND(buf, 200000, MPI_INTEGER, dest, 0,
&          MPI_COMM_WORLD, REQUEST, ierror)
MPI_RECV(buf_tmp, 200000, MPI_INTEGER, source, 0,
&        MPI_COMM_WORLD, status, ierror)
MPI_WAIT(REQUEST, STATUS, ierror)
buf=buf_tmp
```

- **Communication models for non-blocking communication**

Non-Blocking Operation	MPI call
Standard send	<code>MPI_ISEND()</code>
Synchronous send	<code>MPI_ISSEND()</code>
Buffered send	<code>MPI_IBSEND()</code>
Ready send	<code>MPI_IRESEND()</code> <i>DO NOT USE</i>
Receive	<code>MPI_IRECV()</code>

Collective Communication in MPI

Programming Distributed-Memory Architectures

Collective Communication: Introduction

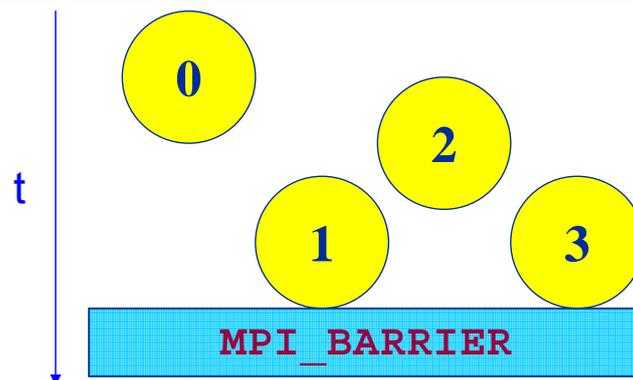

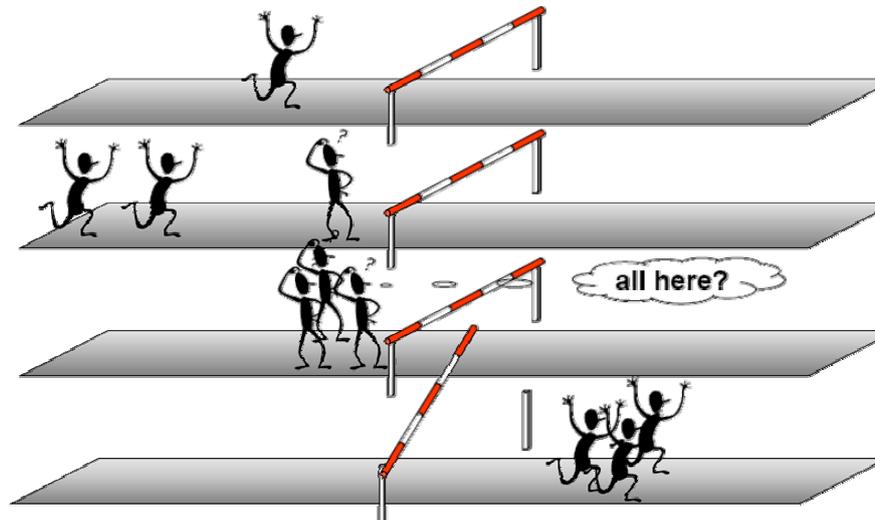

Collective communication always involves every process in the specified communicator

- **Features:**
 - **All processes must call the subroutine**
Remarks:
 - **All processes must call the subroutine!**
 - **All processes must call the subroutine!!**
 - **Always blocking: buffer can be reused after return**
 - **May or may not synchronize the processes**
 - Cannot interfere with point-to-point communication
 - **Datatype matching**
 - **No tags**
 - **Sent message must fill receive buffer (count is exact)**
- Can be “built” out of point-to-point communications by hand, however, collective communication may allow optimized internal implementations, e.g., tree based algorithms

Synchronize processes (MPI_BARRIER):
At this point of the runtime all processes have to wait
until the last one reaches a barrier

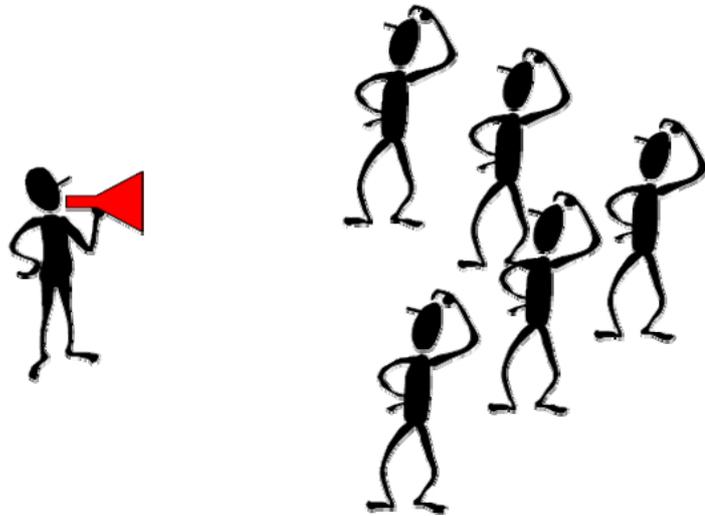

- **Syntax:**
`MPI_BARRIER(comm, ierror)`
- **MPI_BARRIER** blocks the calling process until all other group members (=processes) have called it.
- **MPI_BARRIER** is normally never needed – all synchronization is done automatically by the data communication – however: debugging, profiling, ...

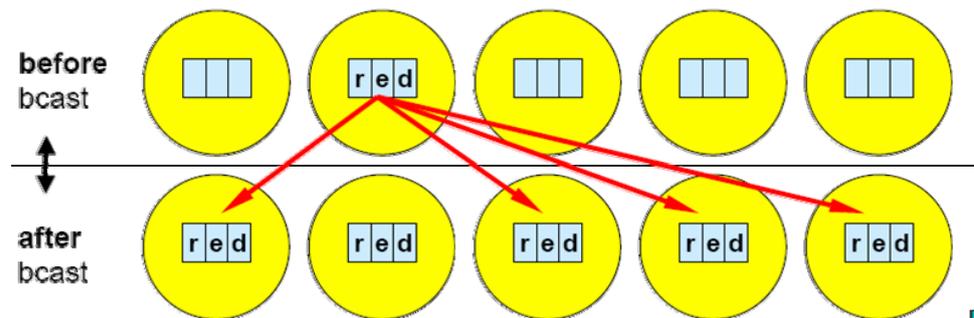

BROADCAST (MPI_BCAST): A one-to-many communication.

- Every process receives one copy of the message from a root process

Syntax

`MPI_BCAST(buffer, count, datatype, root, comm, ierror)`

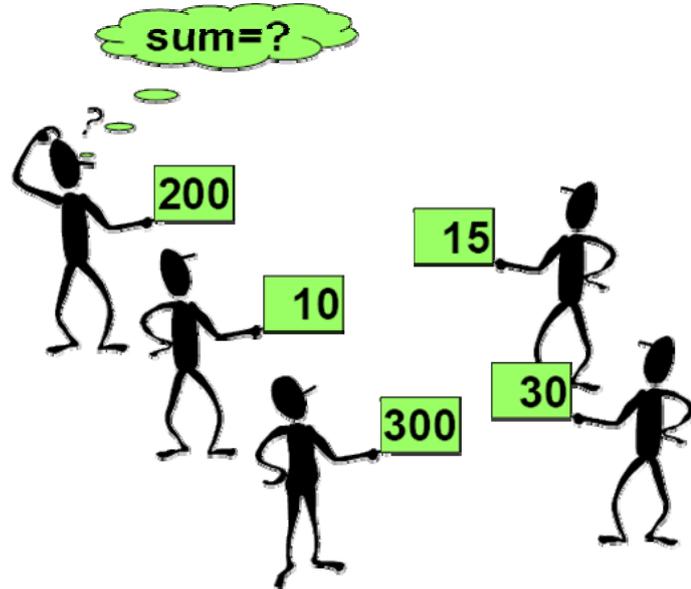

(e.g.: root = 0, but there is no "default" root process)

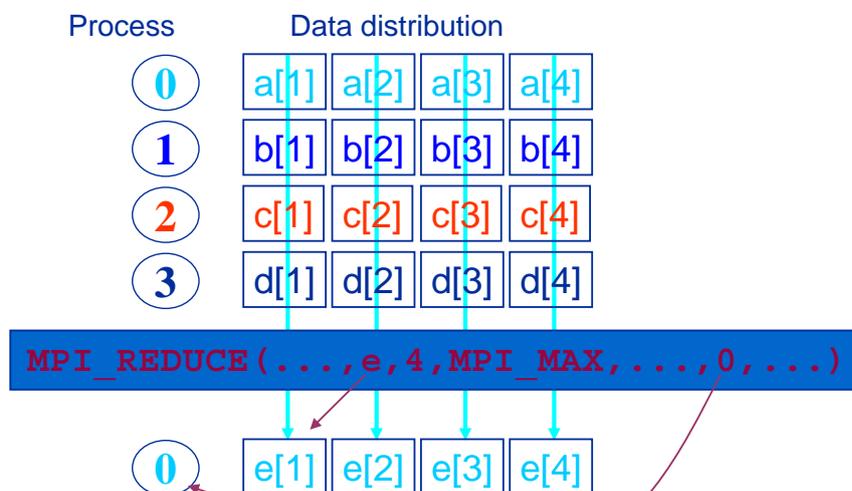

REDUCTION (MPI_REDUCE):

Combine data from several processes to produce a single result.

Compute $e(i) = \max\{ a(i), b(i), c(i), d(i) \}$
 $i=1, 2, 3, 4$

- **Results stored on root process**
`MPI_REDUCE`(sendbuf, recvbuf, count, datatype, op, root, comm, ierror)
- **Result in recvbuf on root process.**
- **Status of recvbuf on other processes is undefined.**
- **count > 1: Perform operations on all 'count' elements of an array**

If results should be stored on all processes:

- **MPI_ALLREDUCE: No root argument**
 - **Combination of MPI_REDUCE and MPI_BCAST**

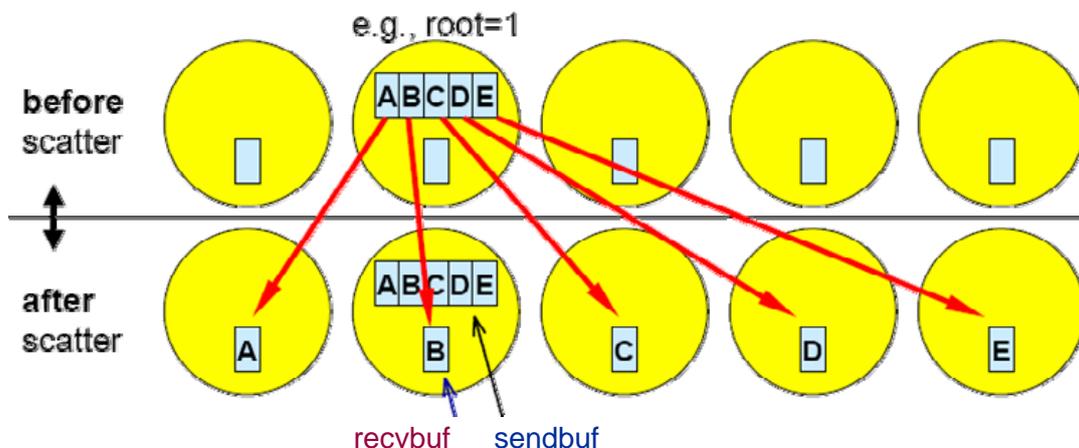

Predefined operations in MPI

Name	Operation	Name	Operation
MPI_SUM	Sum	MPI_PROD	Product
MPI_MAX	Maximum	MPI_MIN	Minimum
MPI_LAND	Logical AND	MPI_BAND	Bit-AND
MPI_LOR	Logical OR	MPI_BOR	Bit-OR
MPI_LXOR	Logical XOR	MPI_BXOR	Bit-XOR
MPI_MAXLOC	Maximum+ Position	MPI_MINLOC	Minimum+ Position

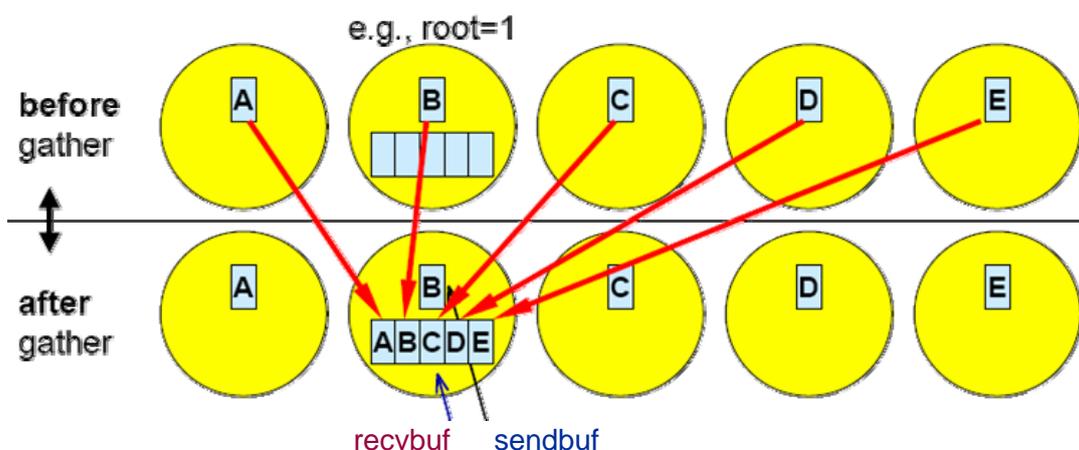

▪ Root process scatters data to all processes

- Specify root process (cf. example : root=1)
- send and receive details are different
- **SCATTER:** send-arguments significant only for root process

▪ Root process gathers data from all processes

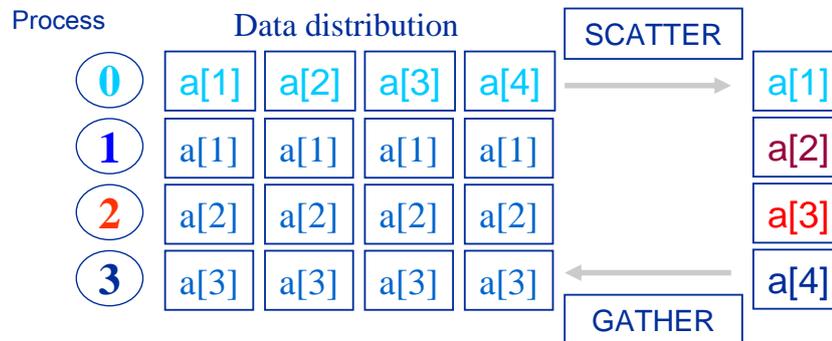

- Specify root process (cf. example : root=1)
- send and receive details are different
- **GATHER:** receive-arguments significant only for root process

Gather / Scatter operations:

Root process scatters/gathers data to/from all processes

- Specify root process (cf. example : **root=0**)
- send and receive details are different
- **GATHER:** **recv-arguments significant only for root process**
- **SCATTER:** **send-arguments significant only for root process**

- **Gather:**
`MPI_GATHER(sendbuf, sendcount, sendtype,
recvbuf, recvcount, recvtype, root, comm,
ierror)`
- Each process sends **sendbuf** to root process
- root process receives messages and stores them in rank order
- In general: **recvcount** = **sendcount**
- **recvbuf** is ignored for all non-root processes

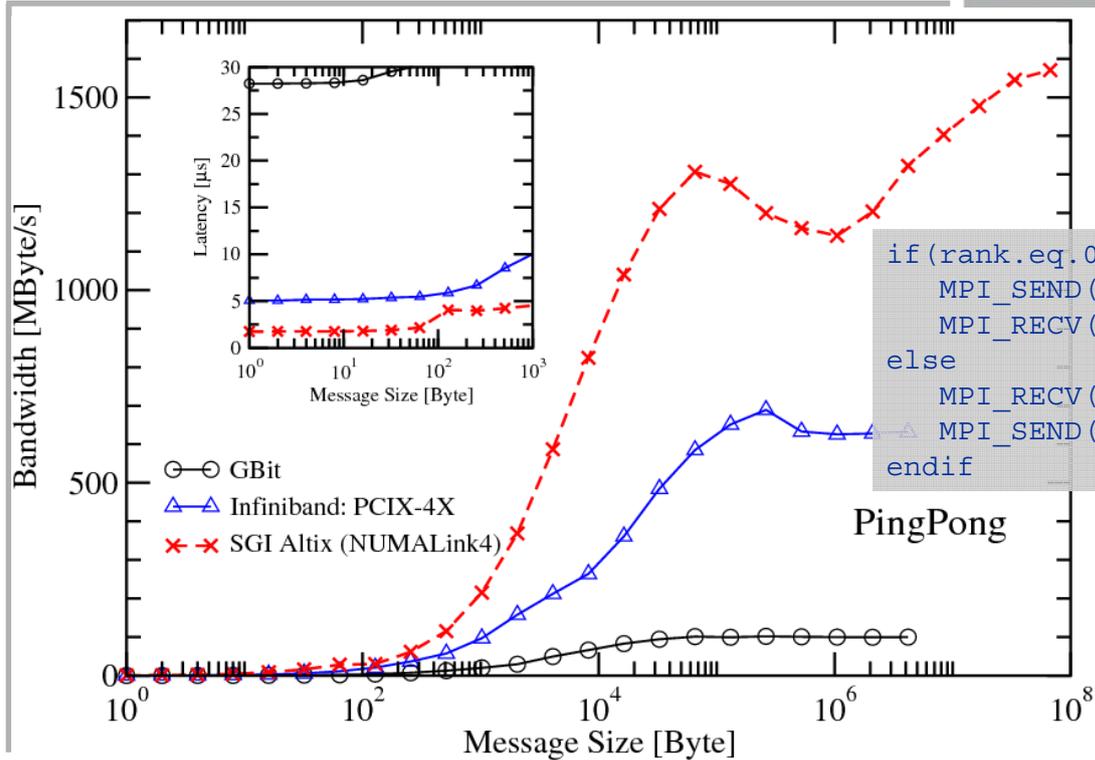

- **Scatter:**
`MPI_SCATTER(sendbuf, sendcount, sendtype,
recvbuf, recvcount, recvtype,
root, comm, ierror)`
- **root process sends the *i*-th. segment of sendbuf to the *i*-th. process**
- **In general: `recvcount = sendcount`**
- **sendbuf is ignored for all non-root processes**

		Point to Point	Collective
Can be mixed, e.g. MPI_Send can be matched by appropriate MPI_Recv(...)	Blocking	MPI_SEND (mybuf...) MPI_SSEND (mybuf...) MPI_BSEND (mybuf...) MPI_RECV (mybuf...) (mybuf can be modified after call returns)	MPI_BARRIER (...) MPI_BCAST (...) MPI_ALLREDUCE (...) (All processes of the communicator must call the operation!)
	Non-blocking	MPI_ISEND (mybuf...) MPI_IRECV (mybuf...) (mybuf must not be modified after call returns – requires additional check for completion e.g.:MPI_Wait/Test)	---

MPI Exercise

MPI Exercise: *Matrix-Vector Multiply*

- **Dense matrix vector multiply:**
 - Common operation with eigenproblems
- **Mathematically:**

$$c_i = c_i + \sum_j A_{ij} r_j \quad (i, j=1, \dots, n_dim)$$

- **Serial code:**

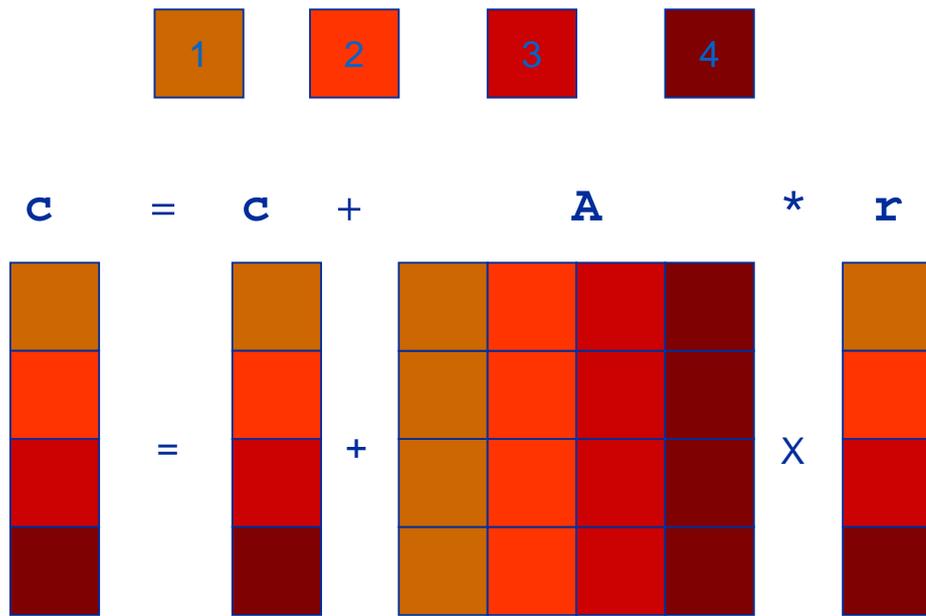

```
do i = 1 , n_dim
  do j = 1 , n_dim
    c( i ) = c( i ) + A( i , j ) * r( j )
  enddo
enddo
```

- **No reference to RISC optimizations here...**
- **Exercise: Implement parallel dense MVM**

MPI Exercise:
Matrix-Vector Multiply

- **Distribution of matrix and vector among the processors**

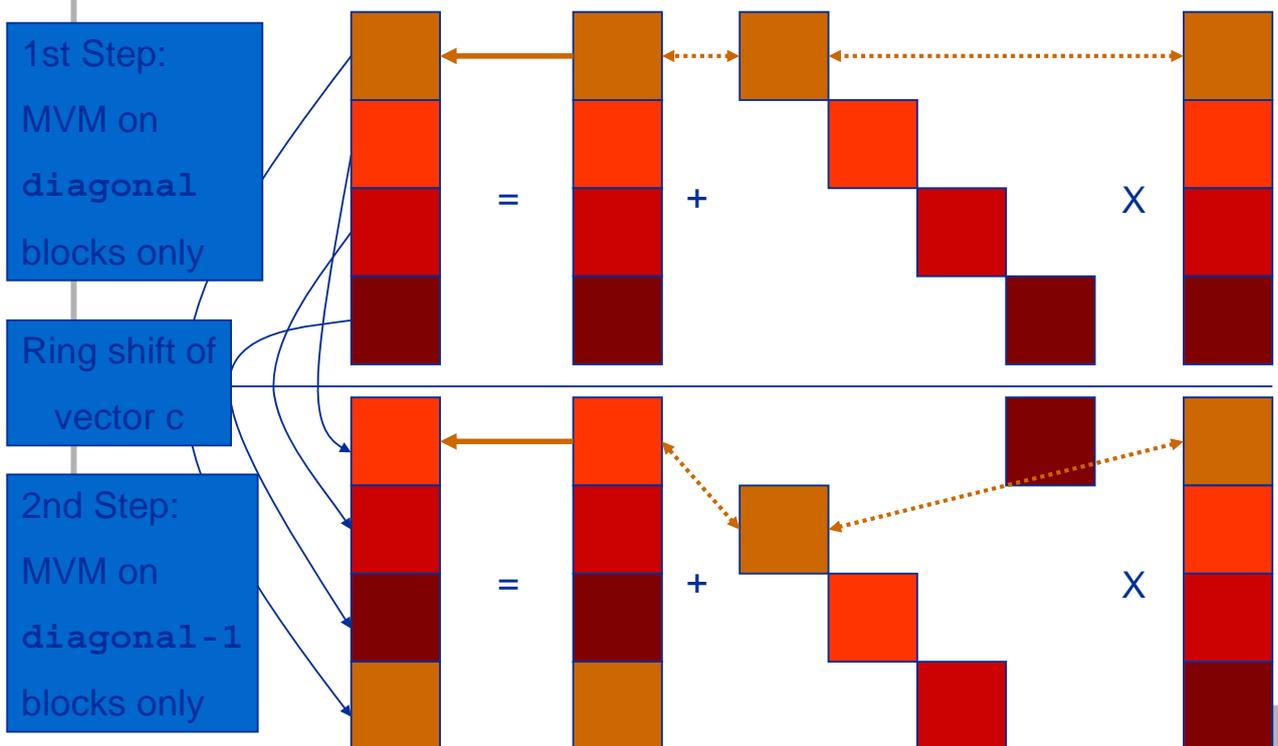

Parallelrechner – Vorlesung im SS2007

(67)

MPI Exercise:
Matrix-Vector Multiply: MPI Parallelization

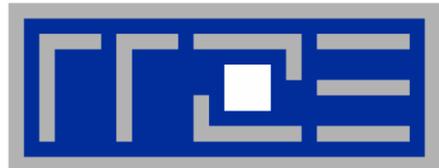

Parallelrechner – Vorlesung im SS2007

(68)

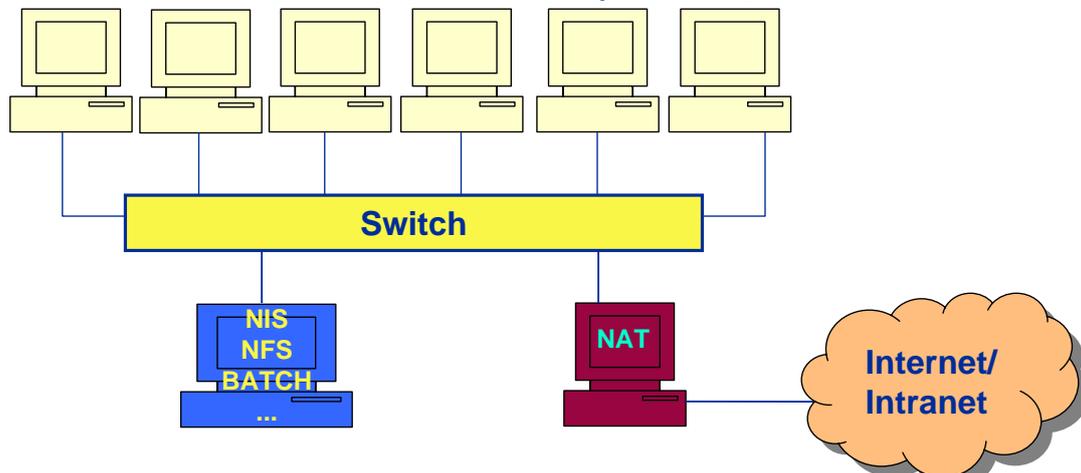

- **After 4 (np) steps:**
 - the total MVM has been computed
 - the distribution of vector c to the processors has been restored
 - Vector c has been communicated np times
- **Communication step (blocking):**
 - Ring-shift with, e.g., `MPI_SEND/MPI_RECV`
- **Communication step (non-blocking):**
 - Idea: overlap communication and computation
 - Spend an additional temporary vector for asynchronous data transfer
 - Use non-blocking communication calls
 - Initialize next communication step before computation and check for completion afterwards
 - Start with `diagonal-1`; end with `diagonal` calculation

Some Hints for Building a Compute Cluster

- **Hardware Setup**
 - **Compute nodes: PCs with (at least) Ethernet**
 - **Switch (preferably non-blocking)**
 - **Network setup with NAT (easy SW updates)**
 - **“Head node”** is gateway to internet / rest of intranet
 - **Server for cluster services (NIS, NFS, DNS, DHCP, batch system)**

- **All systems: Linux/UNIX OS**
- **All systems are NFS clients**
 - **NIS-directed automounter**
 - **\$HOME for all users on common NFS**
- **Compute nodes: Batch system daemon (Torque-MOM)**
- **Frontend/headnode**
 - **Batch system client commands (Torque clients)**
 - **Development SW (compilers, MPI, libs, tools)**
 - **NAT**
- **Server**
 - **Batch system server/scheduler (Torque)**
 - **NFS server**
 - **NIS server**
 - **DHCP server**
 - **DNS server/slave**
 - **Ganglia Monitoring Suite**

- **Non-standard software:**
- **Compilers (GNU gcc/g++/g77/gfortran or Intel or...)**
- **MPI**
 - **Free implementation MPICH:**
<http://www-unix.mcs.anl.gov/mpi/>
 - `./configure` for use with compiler of your choice
 - Install static libs on frontend, dynamic libs (if built) on nodes
 - “make install” also installs MPI compiler scripts (mpicc...)
 - Might want to consider Pete Wyckoff’s mpiexec for program startup
<http://www.osc.edu/~pw/mpiexec/index.php>
 - MPI requires a node list (or file) to find the nodes to run processes on
 - batch system selects nodes automatically

- **Batch system**
 - **Torque: Terascale Open-Source Resource and QUEue Manager**
<http://www.clusterresources.com/pages/products/torque-resource-manager.php>
 - Torque comes with a simple standard scheduler
 - Client commands (qsub, qstat, ...), server (pbs_server), MOM (pbs_mom) and scheduler (pbs_sched) can be built separately
 - Server and scheduler go to server node, clients go to headnode, MOM goes to all compute nodes
 - Torque requires node file with list of nodes and properties:

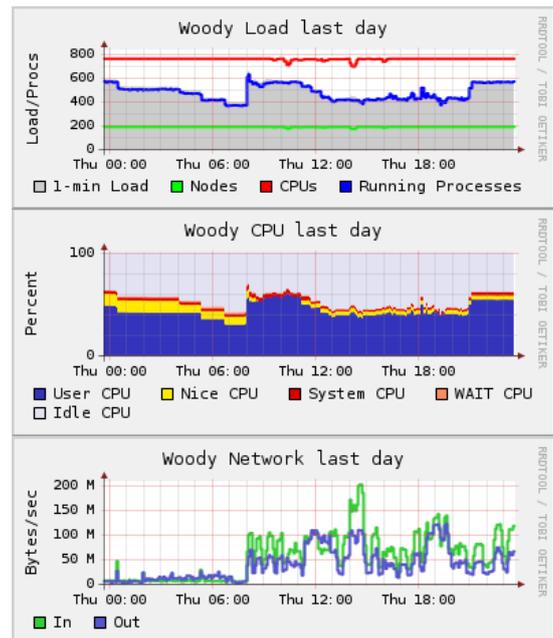

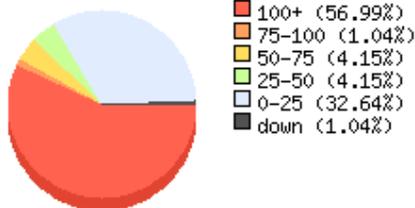

```
w0101 np=4 rack01 ib
w0102 np=4 rack01 ib
w0103 np=4 rack01 ib
w0104 np=4 rack01 ib
```
 - Torque controls health state of all nodes

- **Ganglia Monitoring System**
<http://ganglia.sourceforge.net>
- **Stores and visualizes many metrics, global and node-based**
- **Highly configurable**
- **Integrates Torque**
 - Job data
 - Job history

Cluster Load Percentages

- **For compute center quality of service, some elements have to be added**
 - **Cooling**
 - **Failure monitoring:** Nodes and services going down must lead to admin notifications
 - **Accounting:** Who has drawn how much CPU time over some period?
 - **Regular updates:** Scheduled downtimes
 - **Tools:** Parallel debuggers, profilers
 - **Documentation for users**
